

IASST synthesises new compound to combat aggressive breast cancer

03 September 2025 | News

Organoselenium compounds, some sourced from plants and others, synthesised in the lab are gaining attention for their biological activities

A newly designed nitro-substituted organoselenium compound by Guwahati-based Institute of Advanced Study in Science and Technology (IASST), an autonomous institute under the Department of Science and Technology (DST), can reduce the invasiveness of aggressive triple-negative breast cancer cells by modulating various signalling pathways.

The team synthesised it via nucleophilic substitution of benzylic halides with Na_2Se and NaHSe , obtained by reducing elemental selenium with sodium borohydride under an inert atmosphere.

This newly synthesized nitro-substituted organoselenium compound, called diselenide 7, was found to reduce the invasiveness of aggressive triple-negative breast cancer cells by modulating various signaling pathways. In Swiss albino mice with breast adenocarcinoma, it significantly decreased tumour volume and reduced angiogenesis and metastasis, extending the animals' lifespan.

Investigations revealed that the compound exerts its anticancer effect by targeting multiple survival mechanisms within cancer cells. This treatment blocks two important pathways, Akt/mTOR and ERK, that help cancer cells grow and are critical for uncontrolled cell growth. It also creates reactive oxygen species (ROS) and reduces inflammation, which can damage DNA and harm the cancer cells, leading to cell death.

This study highlights the role of nitro-substituted organoselenium compounds as multitargeting anticancer agents, supporting their development for effective cancer treatment.
